While batteries and capacitors are both energy storage devices, they differ in some key aspects. A capacitor utilizes an electric field to store its potential energy, while a battery stores its energy in chemical form. Battery technology offers higher energy densities, allowing them to store more energy per unit weight than capacitors.

Capacitors used for energy storage. Capacitors are devices which store electrical energy in the form of electrical charge accumulated on their plates. When a capacitor is connected to a power source, it accumulates energy which can be released when the capacitor is disconnected from the charging source, and in this respect they are similar to batteries.

Yet the energy-storage density of dielectric capacitors is usually relatively low compared with other energy-storage systems. If the energy density of dielectric capacitors can be comparable to that of electrochemical capacitors or even batteries, their application ranges in the energy-storage field will be greatly expanded.

Capacitor - Energy Stored. The work done in establishing an electric field in a capacitor, and hence the amount of energy stored - can be expressed as. $W = \frac{1}{2} C U^2$ (1) where . W = energy stored - or work done in establishing the electric field (joules, J) C = capacitance (farad, F, μF) U = potential difference (voltage, V) Capacitor - Power
