When the amount of energy generated by a grid- connected PV system exceeds the customer's loads, excess energy is exported to the utility, turning the customer's electric meter backward. Conversely, the customer can draw needed power from the utility when energy from the PV system is insufficient to power the building's loads.

These principles address key issues such as material sustainability, service life, and environmental performance of grid generations" assets. An algorithm is developed to deploy the design principles of energy storage systems that meet various grid applications. This process takes into account the service that the energy storage would provide.

The subsystem represented in Figure 1(a) could be one of a final user of the electric energy of a full power system. The subsystem represented in Figure 1(b) could be one of a small power plant working as distributed generation (DG). Most of these power systems operate only when connected to a full power system.
