# WHAT IS MICROGRID POWER CONTROL

Microgrids consist of three main components: power sources, power storage, and loads. Power sources are the different ways that electricity is generated with the microgrid and can include solar panels, wind turbines, or other renewable energy sources. These sources produce electricity to power the microgrid.

Microgrids include renewable power generation, distribution and control. Generally, they will use renewable energy sources such as solar or wind. This energy is then saved in a storage system, normally batteries. An intelligent control centre, or controller, then regulates the energy flow balancing out demand to ensure the system remains in

The power control DC microgrid structure has to be designed following PN modeling. This interface includes the operation criteria such as on-grid or off-grid as well as smart grid message communication. The implemented algorithms are supposed to calculate power references for sources with respect to their limitations and the load shedding
